Data I/O, Part 1

Data Wrangling in R

Explaining output on slides

In slides, a command (we'll also call them code or a code chunk) will look like this

```
print("I'm code")
```

```
[1] "I'm code"
```

And then directly after it, will be the output of the code. So print ("I'm code") is the code chunk and [1] "I'm code" is the output.

These slides were made in R using knitr and R Markdown which is covered in later today when we discuss reproducible research.

- · 'Reading in' data is the first step of any real project/analysis
- · R can read almost any file format, especially via add-on packages
- We are going to focus on simple delimited files first
 - tab delimited (e.g. '.txt')
 - comma separated (e.g. '.csv')
 - Microsoft excel (e.g. '.xlsx')

UFO Sightings via Kaggle.com: "Reports of unidentified flying object reports in the last century".

"There are two versions of this dataset: scrubbed and complete. The complete data includes entries where the location of the sighting was not found or blank (0.8146%) or have an erroneous or blank time (8.0237%). Since the reports date back to the 20th century, some older data might be obscured. Data contains city, state, time, description, and duration of each sighting."

https://www.kaggle.com/NUFORC/ufo-sightings

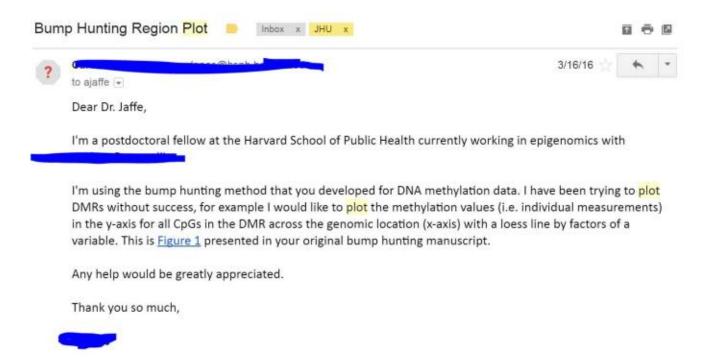

- Download data from http://sisbid.github.io/Module1/data/ufo/ufo_data_complete.csv.gz
- Upload the data to RStudio Cloud

Easy way: R Studio features some nice "drop down" support, where you can run some tasks by selecting them from the toolbar.

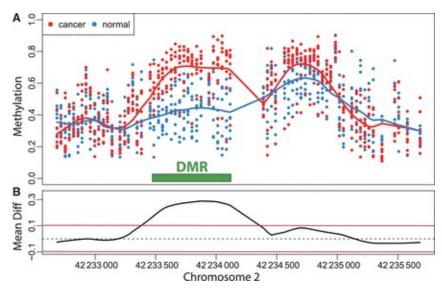

For example, you can easily import text datasets using the "Tools -> Import Dataset -> From Text (readr)" command. Selecting this will bring up a new screen that lets you specify the formatting of your text file.

After importing a dataset, you get the corresponding R commands that you can enter in the console if you want to re-import data.

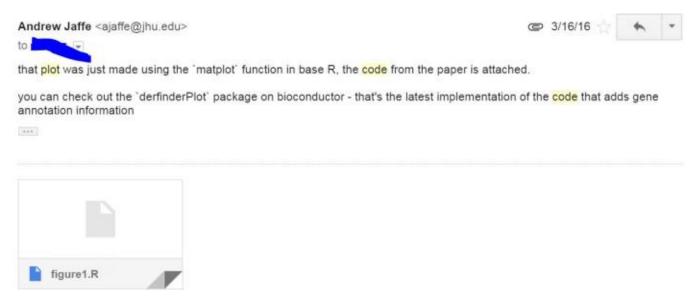

Commenting in code is super important. You should be able to go back to your code years after writing it and figure out exactly what the script is doing. Commenting helps you do this. This happens to me often...

The paper came out January 2012 with code made in 2011

This was the figure...

After some digging, I found the code

Add a comment header to your script from today:# is the comment symbol

R variables

- You can create variables from within the R environment and from files on your computer
- R uses "=" or "<-" to assign values to a variable name
- · Variable names are case-sensitive, i.e. X and x are different

```
x = 2 # Same as: x <- 2
x

[1] 2
x * 4

[1] 8
x + 2</pre>
```

Help

For any function, you can write ?FUNCTION_NAME, or help("FUNCTION_NAME") to look at the help file:

```
?dir
help("dir")
```

Initially-harder-but-gets-way-easier method: Utilizing functions in the readr package called read_delim() and read_csv() with code.

- · The filename is the path to your file, in quotes
- The function will look in your "working directory" if no absolute file path is given
- Note that the filename can also be a path to a file on a website (e.g. 'www.someurl.com/table1.txt')

There is another convenient function for reading in CSV files, where the delimiter is assumed to be a comma:

 Here would be reading in the data from the command line, specifying the file path:

```
ufo = read csv("../data/ufo/ufo data complete.csv")
Parsed with column specification:
cols(
  datetime = col character(),
  city = col character(),
  state = col character(),
  country = \overline{col} character(),
  shape = col character(),
  `duration (\overline{\text{seconds}})` = col double(),
  `duration (hours/min)` = \overline{col} character(),
  comments = col character(),
  `date posted` = col character(),
  latitude = col character(),
  longitude = col \overline{l} double()
Warning: 199 parsing failures.
 row col expected
                         actual
                                                                   file
 877 -- 11 columns 12 columns '../data/ufo/ufo data complete.csv'
1712 -- 11 columns 12 columns '../data/ufo/ufo data complete.csv'
1814 -- 11 columns 12 columns '../data/ufo/ufo data complete.csv'
2857 -- 11 columns 12 columns '../data/ufo/ufo data complete.csv'
                                                                           18/25
3733
     -- 11 columns 12 columns '../data/ufo/ufo data complete.csv'
```

The read_delim() and related functions returns a "tibble" is a data.frame with special printing, which is the primary data format for most data cleaning and analyses.

```

There are also data importing functions provided in base R (rather than the readr package), like read.delim and read.csv.

These functions have slightly different syntax for reading in data, like header and as.is.

However, while many online resources use the base R tools, recent versions of RStudio switched to use these new readr data import tools, so we will use them in the class for slides. They are also up to two times faster for reading in large datasets, and have a progress bar which is nice.

Data Input - Excel

Many data analysts collaborate with researchers who use Excel to enter and curate their data. Often times, this is the input data for an analysis. You therefore have two options for getting this data into R:

- Saving the Excel sheet as a .csv file, and using read_csv()
- Using an add-on package, like readx1, the read_excel function

For single worksheet .xlsx files, better to keep the XLSX file as the raw data as Excel exporting CSV can make slight changes (but I often have to strip off additional summary data from the columns).

Data Input - Other Software

- haven package (https://cran.r-project.org/web/packages/haven/index.html)
 reads in SAS, SPSS, Stata formats
- sas7bdat reads .sas7bdat files
- **foreign** package can read all the formats as **haven**. Around longer (aka more testing), but not as maintained (bad for future).

Common new user mistakes we have seen

- 1. Working directory problems: trying to read files that R "can't find"
 - · RStudio can help, and so do RStudio Projects
 - discuss in this Data Input/Output lecture
- 2. Lack of comments in code
- 3. Typos (R is case sensitive, x and x are different)
 - RStudio helps with "tab completion"
 - discussed throughout
- 4. Data type problems (is that a string or a number?)
- 5. Open ended quotes, parentheses, and brackets
- 6. Different versions of software

Working Directories

- R "looks" for files on your computer (or cloud) relative to the "working" directory
- Many people recommend not setting a directory in the scripts
 - assume you're in the directory the script is in
 - If you open an R file with a new RStudio session, it does this for you.
- If you do set a working directory, do it at the beginning of your script.
- Example of getting and setting the working directory:

```
## get the working directory
getwd()
setwd("~/Lectures")
```
